Summary

LLMOrchestrator is a Python package for studying Large Language Models by orchestrating multiple models in defined roles—generation, verification, and refinement. It integrates API-based and local models (e.g., OpenAI, Hugging Face Transformers) under a unified workflow. Researchers can manage prompts, execute iterative reasoning loops, and monitor performance metrics like processing times and quality scores to uncover biases and emergent behaviors. The framework simplifies complex experiments through prompt templates, parallel execution, and caching, enabling reproducible, transparent analysis for AI safety, multi-agent simulations, and model benchmarking.

Statement of Need

Research on LLMs extends beyond single prompts; it demands diverse perspectives, rigorous validation, and multi-step reasoning. **LLMOrchestrator** offers a flexible environment supporting custom workflows, systematic verification, and comparative studies, helping researchers navigate experimental complexity with reproducibility and efficiency.

Core Capabilities

The framework abstracts models via `OpenAIModel` and `LocalModel` classes that handle API calls or local inference, and supports custom generators and verifiers using Python-based logic or LLMs for generation and evaluation. Controlled iterative refinement loops use `max_iterations` and `max_verifications`, while `PromptTemplate` manages systematic prompt variation. `ValidationMetrics` track token counts, runtimes, and verifier scores, and `execute_parallel` with `OutputCache` accelerates scalable experiments. # Architecture Overview

Controller

The Controller orchestrates experiments. Instantiate with generator, verifier, and iteration settings:

```
from LLMOrchestrator.controller import Controller
controller = Controller(
    generator=generator_model,
    verifier=verifier_logic,
    max_iterations=5,
    max_verifications=3,
    monitoring_enabled=True
)
```

29 Models

30 Use `OpenAIModel(model_name)` for API calls or `LocalModel(model_name, device)` for local
31 inference. Mix and match for diverse roles.

32 Generator & Verifier

33 Define generation and evaluation logic. Example verifier checks required keywords:

```
def keyword_check(text, prompt=None):  
    keywords = ['research', 'llm', 'framework']  
    passed = all(kw in text.lower() for kw in keywords)  
    return passed, ('{"score":1.0}' if passed else '{"score":0.0}')
```

keyword_verifier = Verifier(custom_verifier=keyword_check)

34 Iteration Loop

35 `Controller.execute()` runs generation and verification steps, refining or retrying based on
36 outcomes until limits are reached.

37 Experimentation & Analysis

38 Metrics Collection

39 Enable `monitoring_enabled` to gather `ValidationMetrics`. Retrieve via `controller.get_validation_m`
40 or `controller.get_performance_report()`.

41 Parallel Experiments

42 Run multiple prompts concurrently:

```
prompts = ['Explain AI safety.', 'Study bias reduction.']  
results = controller.execute_parallel(prompts, max_workers=4)
```

43 Caching

44 Use `OutputCache` during development to avoid redundant model calls.

45 Conclusions

46 LLMOrchestrator offers a modular, reproducible framework for orchestrating multiple LLMs,
47 iterative reasoning, and comprehensive performance tracking. It facilitates diverse, validated
48 insights across models, empowering research in AI safety, multi-agent simulations, and reliability
49 studies.
